(54) Title: METHOD FOR IMPROVING THE OPERATING RELIABILITY OF A REEL-UP

WO 01/77766 A1

(57) Abstract: The invention relates to a method for improving the operating reliability in reeling up of a paper web, in which a continuous paper web which is passed from a paper machine and/or finishing treatment of paper and whose width corresponds to the production width or which is slit into part webs is reeled around a reeling core/reeling cores into successive machine reels or customer rolls. According to the invention, the actual control system controlling the reeling up process is supplemented with a substantially separate, model-based learning fault diagnostics. In a learning state the fault diagnostics learns in the normal operating modes of the reel-up the normal dependencies of the measuring, control and actuating variables of the reel-up by monitoring the

same. In a diagnostic state the fault diagnostics detects the malfunctions in components critical in view of the operation of the reel-up by monitoring the measuring, control and actuating variables and comparing them with the model formed in the learning state. After the fault diagnostics has detected a fault, said fault diagnostics shifts into a fault tolerance state, if necessary, in which, if a fault occurs in a component/some components of the reel-up, the fault diagnostics actively affects the measuring, control and actuating variables to maintain the function of the reel-up, compensating on the basis of the learned model the malfunction caused by the fault/faults in the actual control system as well as in the function of the reel-up.

Method for improving the operating reliability of a reel-up

The invention relates to a method for improving the operating reliability in reeling up of a paper web according to the preamble of the appended
5 claim 1.

A continuous paper web coming from a paper machine or from a finishing apparatus connected thereto in a continuous, i.e. on-line type manner, is reeled in the reel-up into successive machine reels. The
10 machine reels can be seen as a kind of an intermediate storage for the paper web, in which the paper web is stored in the end of a continuous manufacturing process that precedes reeling up. Reeling up is also used in connection with off-line type finishing processes (e.g. calendering, coating) to reel a full-width paper web into machine reels again
15 after the unwinding conducted in the beginning of said process and the treatment/treatments following thereafter. If the web is slit into part webs in connection with these finishing processes, the results of the reeling up are narrower so-called customer rolls that correspond to the width of the part webs.

20 Because the reeling up is an essential part of the treatment of the paper web/webs at one or several stages of the production and finishing processes of paper, the operation and operating reliability of the reel-up is thus a significant factor in view of the overall function of said processes. The entire reeling up process should be implemented in such a
25 manner that it does not cause disturbances (e.g. stoppages) in the function of the other parts of the process. In addition, the properties and quality (hereinbelow referred to as reeling quality) of the paper web to be reeled up should not be weakened during the reeling up itself or as a
30 result of the same at later stages of the process.

The aim to better control the reeling up process and to attain a better operating reliability and a uniform reeling quality has led up to the development of the mechanical functions of the reeling apparatuses
35 themselves as well as the control methods controlling these functions.

CONFIRMATION COPY

The structure and function of the reel-ups currently in use are described for example in the book by Mikko Jokio: Papermaking Part 3 Finishing, published by Fapet Oy, ISBN 952-5216-10-1, 1999, pp. 143-235.

- 5 In the most advanced, so-called second generation reel-ups (see e.g. Papermaking Part 3 Finishing, pp. 160-165), the most important parameters to be adjusted during the actual reeling up sequence, i.e. reel formation, are the web tension of the paper web passed to the reeling, the pressing force, i.e. so-called nip force between a so-called reeling cylinder that guides the web on the roll and the paper reel that is being formed, as well as the torque of the centre-drive of the reeling core of the paper roll. To attain the desired reeling quality for the paper web and desired treatment properties for the reel that is being produced, these parameters are not necessarily kept constant during the reeling up process, but they are adjusted in connection with the same paper grade as a function of the amount of paper accumulated on the reeling core, and for paper grades that differ from each other it is possible to use different parameter values that change in different ways as a function of the amount of paper accumulated on the reeling core.
- 10
- 15
- 20 During the reeling up sequence the increase in the number of adjustable parameters as well as the aim to better optimize said parameters during reeling also increases the requirements for the control methods used for controlling the reeling up. For example, the international publication WO 99/50719 discloses a control method that utilizes neural network computation to produce optimal control variables for a reeling apparatus of paper during the reeling up sequence according to the desired reeling quality at a given time.
- 25
- 30 In addition to the adjustments made during the actual reeling up sequence, the reeling up apparatus conducts a change sequence after the reel/reels have been finished, in which the finished roll/rolls is/are transferred away from the reel-up and at the same time a new reeling core/new reeling cores are brought therein and the web/webs are threaded on said reeling core/cores and after the cutting of the web/webs the reeling up is continued thereon. This change sequence also involves several mechanical functions and adjustment and control
- 35

measures of the same, as is described for example in Papermaking Part 3, Finishing, pp. 162-163.

- 5 The above-described increase in the mechanical functions of the reel-up and the use of more complex adjustment and control methods also have effects that reduce the overall operating reliability of the reel-up. The simple reason for this is that as the functions of the apparatus and the system are increased, the number of potential points of failure in the system increases as well. This applies especially to measuring sensors
10 and measuring methods necessary in the above-described more complex adjustment and control methods, which are required in larger numbers and for which higher and higher accuracy demands have to be placed at the same time.
- 15 The operating reliability of the reel-up can, of course be improved, if all components that are critical in view of the operation, or at least the components that are most liable to faults, such as for example said measuring sensors, are doubled. It is not, however, technically possible to secure all the components by doubling them, and the drawback of the doubled system is the further increasing complexity as well as significantly higher costs.
- 25 The purpose of the present invention is to present a method for improving the operating reliability of the reel-up of a paper web by using a model-based, learning fault diagnostics which is substantially separate from the actual control system of the reel-up. To attain this purpose, the method according to the invention is primarily characterized in what will be presented in the characterizing part of claim 1.
- 30 The method according to the invention is characterized by the following features that improve the operating reliability and controllability of the reeling up process, which features can be attained without securing the components of the reel-up physically i.e. by doubling the components, and thus the increasing complexity of the system as well as the thereby
35 increasing costs can be avoided.

The fault diagnostics according to the invention learns in a learning state in the normal operating modes of the reel-up, including the change sequences of the full roll/rolls and the empty reeling core/cores, the normal dependencies between the control, measuring and actuating variables of the reel-up by monitoring the same.

In a diagnostic state the fault diagnostics detects the malfunctions of the components which are critical in view of the function of the reel-up by monitoring aforementioned measuring-, control and actuating variables and comparing them to the model formed in the learning state.

10 The malfunctions are detected when they cause, or advantageously already before they cause a substantial weakening or interruption in the function of the reel-up. When the fault diagnostics detect a fault or changes preceding a likely fault, the fault diagnostics warns the user and/or gives an alarm and shifts to a fault tolerance state, if necessary.

15

In the fault tolerance state the fault diagnostics actively affects the measuring and/or control variables to maintain the function of the reel-up, compensating on the basis of the learned model the malfunction caused by the fault/faults in the actual control system as well as in the function of the reel-up.

20 The central advantage of the method according to the invention is that the information required by the fault diagnostics can be collected primarily by means of sensors and measurements of the reel-up itself, which are already in use because of the needs of the actual control system. Fault diagnostics, when implemented separately from the actual control system, can also be easily coupled to different types of control systems to be used in connection with the same.

25

30 The analysis of the collected information by means of developed, learning and self-controlled algorithms enables the detection of a likely fault already before it causes a substantial weakening or interruption in the function of the reel-up.

The measuring and control values calculated on the basis of the model formed on the process by the learning algorithm can be utilized to supplement and replace the function of said damaged components.

- 5 In addition to the learning and diagnostics during the normal reeling up sequence, information on the function of the components is also collected in connection with the change sequence of the full roll/rolls and/or the empty reeling core/cores, which takes place at fixed intervals. The masses of the full roll/rolls and/or the empty reeling
10 core/cores as well as the masses of the members moved during the change sequence are substantially known, wherein the force and frictions required in the transfer of the same can be predicted when the components of the apparatus function normally, and thus, during the transfer movement this information can be used for controlling the condition of the components that conduct and/or control and/or monitor the
15 transfer movement. By comparing the changes in the measuring, control and/or actuating variables during successive transfer movements within a longer period of time it is possible to obtain information on the changes occurring in the components participating in the transfer
20 movement.

In the following, the invention will be described in more detail by means of examples and with reference to the appended drawing, in which

- 25 Fig. 1 shows the method according to the invention in a block chart when it functions in a learning state and is arranged in connection with a specific function of the reel-up which will be described in more detail in the text,
- 30 Fig. 2 shows a situation corresponding to Fig. 1 with a distinction that instead of the learning state the fault diagnostics functions in a diagnostic state,
- 35 Fig. 3 shows a situation corresponding to Figs. 1 and 2 in a block chart with a distinction that the fault diagnostics functions in a fault tolerance state, and

6

Fig. 4 illustrates in a side-view the act of applying the method according to the invention in different functions of the reel-up.

The function shown as an example in Fig. 1 consists of a control unit
5 CU, which, after receiving from the actual control system CS a control value 1 indicating a desired force effect, transmits a control variable 2 to a hydraulic valve VA. In the hydraulic valve VA the opening of the valve stem which is indicated by a measured value 3 is adjusted in such a manner that the stem releases from a pressure accumulator,
10 hydraulic pump or a corresponding known source that is coupled to the feed side of the hydraulic valve, a hydraulic oil flow 4 according to the control variable 2 to a hydraulic cylinder HC. The hydraulic cylinder HC generates a pressure as a result of the hydraulic oil flow 4 inside said cylinder, which pressure is indicated by a measured value 5, said pressure pushing the piston with a force 6. This force is measured by
15 means of a force sensor FM. From the force sensor FM a measured value 7 of the force produced by the hydraulic cylinder HC is fed back to the control unit CU, and through this feedback the control unit aims at adjusting the hydraulic valve VA to attain a desired force 6 according
20 to the control value 1.

In the situation according to Fig. 1, the fault diagnostics operates in a learning state, in which by monitoring the measuring, control and actuating variables (1, 2, 3, 5 and 7) of the system that operates without
25 malfunctions or faults of the components, the fault diagnostics learns the dependencies between said variables.

The aforementioned learning can be model-based in such a manner that the fault diagnostics FD contains a model on the operation of the process to be monitored in the form of mathematical function/functions, and in the learning state the parameters contained in said function/functions are tuned. After the tuning, the function/functions can be utilized to calculate for example the value of the variable 7 by means of the values 1, 2, 3 and 5. If the process to be examined contains a large number of measuring, control and actuating variables to be monitored, and the mutual dependency of these cannot be expressed in the form of a conventional mathematical model, it is possible to attain the learn-

ing algorithm contained in the fault diagnostics also by using so-called neural network computation or so-called fuzzy logic/computation. Further, the model-based learning can also take place by means of a so-called expert system, wherein the dependencies between different 5 measuring, control and actuating variables are represented by means of a set of rules contained in the expert system.

Fig. 2 illustrates the function of the fault diagnostics in a diagnostic state. Thus, the fault diagnostics monitors the variables measured from 10 the process, and compares the values of the same with the values given by the model formed in the learning state. When the fault diagnostics detects that a variable deviates from the values given by the model, the fault diagnostics determines the faulty component and warns the user and/or gives an alarm.

15 Fig. 3 shows the function of the fault diagnostics in a fault tolerance state to which the fault diagnostics has shifted after it has detected a fault. In the fault tolerance state the fault diagnostics produces a simulated variable on the basis of the model it has learned and transmits it actively to a suitable point in the process to maintain the function of the process. In the case of Fig. 3, when a fault has occurred in the force sensor FM, the original measured value 7 is replaced with a simulated measured value 8, which is transmitted to the control unit CU. Thus, despite the fault of the force sensor FM, the function of the hydraulic 20 cylinder HC under the control of the control system can be maintained 25 correct in the accuracy with which the simulated signal 8 corresponds to the original signal 7 in said situation.

30 Fig. 4 illustrates the function of one reel-up type and the components of the same, in connection with which the fault diagnostics according to the invention can be applied.

In the reel-up according to Fig. 4, a paper web is brought to the actual reel spool C1 via a reeling cylinder D, i.e. a so-called nipping cylinder, 35 the paper web being reeled on said reel spool forming a reel R thereon. The pressing force, i.e. so-called nip force between the nipping cylinder D and the reel R to be formed on the reel spool is one of the essential

- parameters to be adjusted in the reeling up process. During the reeling up process this nip force is adjusted by means of a reeling cylinder HC1 that moves a reeling carriage S. The reeling carriage S is connected to the ends of the shaft of the reel spool C1, more precisely to its bearing 5 housings, in which the shaft of the reel spool C1 is arranged to rotate. The end of the hydraulic cylinder HC1 on the side of the reeling carriage S is equipped with a force sensor FM1, which measures the force produced by said hydraulic cylinder in the reeling carriage S, and thereby also the nip force between the reel R and the nipping cylinder D. The adjustment of the nip force produced by the hydraulic cylinder 10 HC1 in a manner described above can be monitored by means of fault diagnostics according to Figs. 1 to 3.
- When the reel R shown in Fig. 4 reaches a desired diameter, i.e. the 15 roll becomes full, the hydraulic cylinder HC1 starts to move the reeling carriage S to the right in the drawing, wherein the reel R moves off the nipping cylinder D and further away from the same. This makes it possible to turn the empty reeling core C2 standing ready in the primary reeling device SR by means of the hydraulic cylinder HC2 to the right 20 around an axis of rotation parallel to the central shaft of the nipping cylinder D, in such a manner that the reeling core C2 finally ends up on the support of its shaft ends and bearing housings arranged in said shaft ends on guides B2. In an alternative solution of prior art the reeling core C2 is lowered on the support of rail carriages which are arranged movable on top of the guides B2. During the aforementioned 25 turning, the empty reeling core C2 is accelerated to a web speed corresponding to the speed of the paper web, and the paper web is cut and a web change to the new reeling core C2 is conducted according to prior art.
- In Fig. 4 the act of bringing the new reeling core C2 to the primary 30 reeling device, the centre drives of said reeling core and the nipping cylinder D and the functions related to the cutting and threading of the paper web W are not described in more detail because they are not part of the invention. The aforementioned functions may be based on 35 suitable solutions of prior art. Furthermore, Fig. 4 does not describe the centre-drive of the reel R, the act of slowing down the rotating speed of

the finished roll or other corresponding functions required for transferring the reel R away from the guides B2 because they do not fall within the scope of the invention. The reeling core C1 and C2 may be arranged to rotate in bearing housings etc. by means of prior art
5 solutions, and said bearing housings can move on the support of the guides B2, either directly on top of the guides or on the support of rail carriages arranged movable on said guides. Furthermore, the guides B2 may be arranged in such a manner that the reeling core/reel moves part of the way on the support of the rail carriage and/or reeling
10 carriage, and part of the way on the support of the reeling carriage, or only on the support of the guides B2.

The use of fault diagnostics according to the invention is not, of course, restricted only to the monitoring of the adjustment of the nip force produced by the hydraulic cylinder HC1 shown in Fig. 4. When a full reel R
15 is moved aside (in Fig. 4 to the right on guides B) in the above-described manner by means of the hydraulic cylinder HC1 to restart reeling on the new reeling core C2, it is possible to monitor the condition and perform the fault diagnostics of the components participating in the
20 transfer movement in the ways described hereinbelow.

When the total mass of the full reel R is substantially known, the force required in the transfer of the reel R by means of the hydraulic cylinder HC1 can be predicted and/or measured in a situation where the apparatus functions normally and the frictions related to the movements are normal. When the aforementioned transfer movement is conducted, it is possible to monitor the reading of the force sensor FM1 (and the reading of a corresponding sensor on the other side of the apparatus, on the other end of the reel) during said transfer movement, and if it is observed that the reading deviates from the predicted one and/or from the value measured earlier, it is possible to conclude that a fault has occurred in the force sensor or a change has occurred in the forces required in producing the transfer movement. To locate the fault more accurately, it is possible to use hydraulic pressure (in Figs. 1 to 3 the
25 measured variable 5) measured from the hydraulic cylinder HC1. When the aforementioned hydraulic pressure is known, it is possible, when the hydraulic cylinder functions normally, to utilize the same to define
30
35

10

the force produced by the hydraulic cylinder, which is compared with the reading given by the force sensor FM1.

When the force sensor operates properly, but force values which are
5 higher than the normal force value are still detected during the transfer movement, the mechanical frictions have been increased either on the guide B1 (support of the reeling carriage S) or on the guide B2 (support of the end bearing housings of the reeling core either directly or via separate rail carriages). When a force sensor FM2 (Fig. 4) is added to
10 measure the force transmitted via locking jaws J in the transfer of the reel R, it is, on the basis of the mutual behaviour of the force measurements, possible to determine whether the friction has increased in the guide B1 or B2. By monitoring the force FM1 required in the return movement of the empty carriage without the weight and friction effect of
15 the full reel R and the reeling core C1, it is possible to obtain further information to find out which guide B1 or B2 caused the detected increase in the force in the transfer movement of the full reel.

The information given by a location sensor PM (Fig. 4) can be used
20 during aforementioned transfer movements in the measurements of friction in such a manner that during the definition of the friction by means of the force measurement the transfer speed of said transfer movement is kept constant by means of the information given by the location sensor PM. Thus, the deviations detected by means of the
25 force measurements FM1, FM2 result precisely from the changes in the frictions and not from the accelerating or decelerating movement.

The value given by the location sensor PM can, on the other hand, be compared to the opening in the valve stem of the hydraulic valve used
30 in the control of the hydraulic cylinder (Fig. 1, measured value 3). Because a given opening of the valve stem produces a fixed volume flow of the hydraulic oil (Fig. 1, variable 4), said opening/volume flow should in a normal situation i.e. without increased frictions and/or leaks in the hydraulic system, correspond to the transfer speed measured from the
35 reading given by the location sensor PM during the transfer movement.

11

In addition to the kinetic friction/frictions measured during the aforementioned transfer movements, fault diagnostics can also be performed by utilizing the transient behaviour of the force/forces required for overcoming the static frictions in the beginning of aforementioned transfer
5 movements. These measurements can be conducted when the transfer of the full reel R is started and in a corresponding manner when the return movement of the reeling carriage S is started. In this situation it is possible to utilize the location sensor PM to determine the acceleration and speed of the movement, by means of which it is possible to
10 define the forces required in this situation in theory, which forces can be further compared to the values given by the force measurement.

It is, of course, obvious that the use of the fault diagnostics according to the invention is not restricted solely to the monitoring of the above-described functions attained by means of the hydraulic cylinder HC1, but in a corresponding manner the fault diagnostics can be utilized in connection with the functions of the primary reeling device SR. In the primary reeling device SR the hydraulic cylinder HC3 adjusts the nip force between the reeling core/early reel C2 and the nipping cylinder D, which nip force is measured with a force sensor FM3. This adjustment of the nip force as well as the fault diagnostics of the same correspond to the situation shown in Figs. 1 to 3. In the primary reeling device SR, the turning of the primary reeling device from the vertical position to the horizontal position by means of a hydraulic cylinder HC2 corresponds
20 to the linear transfer movement of the reel R by means of the hydraulic cylinder HC1. During this movement sequence it is possible to conduct fault diagnostics based on static and kinetic frictions when the reeling core C2 is attached to the primary reeling device, or when the primary reeling device SR moves back into its initial position (vertical position)
25 without the reeling core, preparing itself for receiving a new empty reeling core.
30

When the other ends of the hydraulic cylinders (e.g. HC1, HC3) are supplemented with force measurement as well, and the forces measured from both ends of the hydraulic cylinders correspond to each other (i.e. it can be assumed that said force sensors operate faultlessly), but the force value calculated from the inner hydraulic pressure of said cyl-

12

- inder deviates from the value of aforementioned force sensors, the reason for this is an increase in the inner frictions of the hydraulic cylinders, in other words changes in frictions caused by wearing of the sealing of the cylinder. The aforementioned cylinder friction can be
5 detected by measuring the hydraulic pressure from both ends of the hydraulic piston inside the hydraulic cylinder (e.g. HC1) and comparing the force value calculated therefrom with the reading of the corresponding force sensor (e.g. FM1).
- 10 The fault diagnostics according to the invention, as far as conducted outside the actual reeling up sequence, in other words in connection with a change sequence of the full reel/reels and/or the empty reeling core/cores which is repeated at fixed intervals, can, in addition to the aforementioned normal change sequences, be conducted automatically,
15 if necessary, always when the continuous function of the reel-up has been interrupted as a result of a fault, e.g. web break, that has occurred elsewhere in the production process. The user can also give a command for conducting said diagnostics sequence when the situation so requires/allows.
20 In addition to the dependencies between the above-described measuring, control and actuating variables the fault diagnostics can also monitor the time used for performing the aforementioned different sequences to detect and predict a fault situation, i.e., monitor the transfer
25 time of said sequences. If the duration required by a particular sequence contains for example an increasing trend, an alarm is given after a predetermined alarm limit, and the system shifts to the fault tolerance state, if necessary.
30 Even though the above-described examples for the sake of clarity only refer to a reel-up of a particular type, equipped with functions of particular type, the use of the invention is not restricted solely to the reel-ups according to these examples. According to the inventive aspects described in the claims it is possible to apply the invention also in reel-
35 ups of other types.

13

Furthermore, the use of the invention is not restricted solely to the fault diagnostics of hydraulically implemented functions of the reel-up, but it can be applied in other such functions of the reel-up for the implementation of which functional blocks according to Figs. 1 to 3 are used.

5 These can, for example, include systems related to the adjustment of torque or speed of rotating machines, in which a control unit on the basis of the control value of the adjustment system controls the function of the electric motor by means of an electric adjuster, in which function the torque or the rotating speed are measured by means of a suitable
10 measuring sensor, which gives a signal that is fed back to the control unit. The fault diagnostics according to the invention can be applied according to the same principles for rotating or linear movements controlled by the control system, which movements are implemented hydraulically, electrically or pneumatically.

15 According to the details presented above, the use of the invention is not restricted solely to the control of such components which are the same as the components used during the actual reeling up sequence or primary reeling sequence to produce and adjust nip force, or the
20 components participating in the transfer movement during the change sequence. According to the inventive aspects presented in the claims, the method can also be applied in the fault diagnostics of other components/functions, for example in the monitoring of functions used in centre-drives used in the reel-ups as well as for example in the adjustment
25 of web tension.

Claims:

1. Method for improving the operating reliability in reeling up of a paper web, in which a continuous paper web (W) which is coming from a paper machine and/or finishing treatment of paper and whose width corresponds to the width of production or which is slit into part webs, is reeled around a reeling core/reeling cores (C1, C2) into successive machine reels or customer rolls, **characterized** in that in addition to the actual control system (CS) that controls the reeling up, a substantially separate model-based learning fault diagnostics (FD) is used.
5
2. The method according to claim 1, **characterized** in that in a learning state (Fig. 1) the fault diagnostics (FD) learns in the normal operating modes of the reel-up, including the change sequences of the full reel/reels and the empty reeling core/cores, the normal dependencies between the measuring, control and actuating variables (1 to 7) of the reel-up by monitoring the same.
15
3. The method according to claim 2, **characterized** in that in a diagnostic state (Fig. 2) the fault diagnostics (FD) detects the malfunctions of components which are critical in view of the operation of the reel-up by monitoring the measuring, control and actuating variables and comparing them with the model formed in the learning state.
20
4. The method according to claim 3, **characterized** in that by monitoring the measuring, control and actuating variables during a longer period of time and comparing the behaviour and changes in the behaviour of the same with the model formed in the learning state, the fault diagnostics (FD) predicts the malfunctions in the components critical in view of the operation of the reel-up.
25
5. The method according to claims 3 or 4, **characterized** in that after the fault diagnostics (FD) has detected or predicted a fault, said fault diagnostics warns the user and/or gives an alarm.
30
6. The method according to any of the preceding claims, **characterized** in that after a fault is detected the fault diagnostics (FD) shifts into
35

15

a fault tolerance state (Fig. 3), if necessary, in which, if a fault occurs in a component/some components of the reel-up, the fault diagnostics actively affects the measuring, control and actuating variables to maintain the function of the reel-up, compensating on the basis of the model it
5 has learned the malfunction caused by the fault/faults in the actual control system as well as in the function of the reel-up.

7. The method according to any of the preceding claims, **characterized** in that the learning capability of the model-based fault diagnostics
10 (FD) is based on the use of a neural network.

8. The method according to any of the preceding claims, **characterized** in that the learning capability of the model-based fault diagnostics (FD) is based on the use of fuzzy logic/computation.

15 9. The method according to any of the preceding claims, **characterized** in that the learning capability of the model-based fault diagnostics (FD) is based on tuning of the parameters of the function/functions contained in the mathematical model made on the process.

20 10. The method according to any of the preceding claims 1 to 9, **characterized** in that fault diagnostics is conducted for the components related to production, adjustment and measurement of the nip force between the reel (R) formed on the reel spool (C1) and the nipping cylinder (D) during the actual reeling up sequence.
25

11. The method according to any of the preceding claims 1 to 9, **characterized** in that fault diagnostics is conducted for the components related to production, adjustment and measurement of the nip force
30 between the reel (R) formed on the reel spool (C2) and the nipping cylinder (D) during the primary reeling sequence.

12. The method according to any of the preceding claims 1 to 9, **characterized** in that in connection with a change sequence of the full reel (R and C1) and/or empty reeling core/cores at fixed intervals during
35 the transfer movement of the reel/reels and/or reeling core/cores measurements are conducted to define the condition of the compo-

16

nents conducting and/or controlling and/or monitoring the transfer movement.

13. The method according to claim 12, **characterized** in that to conduct the transfer movement belonging to the change sequence, the necessary force/forces are measured by means of a force sensor/force sensors (FM1, FM2, FM3) to check the function of said force sensor/sensors.
- 10 14. The method according to claim 12, **characterized** in that to conduct the transfer movement belonging to the change sequence, the necessary force/forces are measured by means of the force sensor/force sensors (FM1, FM2, FM3) to define the kinetic and static frictions as well as the condition of the components affecting said frictions.
- 15 15. The method according to any of the preceding claims 12 to 14, **characterized** in that instead of/in addition to the force sensor/force sensors the force required for conducting the transfer movement belonging to the change sequence is defined by a measurement of the hydraulic pressure of a hydraulic cylinder (HC1, HC2, HC3) used for producing said force.
- 25 16. The method according to any of the preceding claims 12 to 15, **characterized** in that fault diagnostics of the transfer movement and the components related thereto is conducted when the full reel (R) is transferred away from the area of influence of the nipping cylinder (D) by means of a reeling carriage (S) along guides (B2) (to the right in Fig. 4), and/or reeling (S) without the reel (R) during the return movement (to the left in Fig. 4).
- 30 17. The method according to any of the preceding claims 12 to 15, **characterized** in that fault diagnostics of the transfer movement and the components related thereto is conducted when the primary reeling device (SR) and an empty reeling core (C2) attached thereto are turned from the starting position (vertical position in Fig. 4) to the actual reeling position (towards the guides B in Fig. 4), and/or during the return
- 35

17

movement (back to the vertical position in Fig. 4) of the primary reeling device (SR) without the reeling core (C2).

18. The method according to any of the preceding claims 12 to 17,
5 characterized in that the force member/members (HC1, HC3) used for
conducting the transfer movement belonging to the change sequence
are the same as the force member/members used during the actual
reeling up sequence or the primary reeling sequence for producing nip
force, and further, said force sensor/sensors (FM1, FM3) are the same
10 as the sensors used during the reeling up or the initial reeling in the
measurement of nip force.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/FI 01/00352

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7	G05B13/02	B65H18/26	B65H23/182	B65H26/00	B65H43/00
-------	-----------	-----------	------------	-----------	-----------

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7	G05B	B65H
-------	------	------

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 0 460 892 A (HITACHI LTD) 11 December 1991 (1991-12-11) column 2, line 5 - line 45 column 2, line 53 -column 3, line 10 column 3, line 22 - line 58 abstract column 4, line 27 - line 39 column 7, line 51 - line 56 column 8, line 29 -column 9, line 8 column 11, line 55 -column 12, line 28 column 15, line 20 - line 41 --- WO 99 50719 A (SIEMENS AG) 7 October 1999 (1999-10-07) abstract; claims 1,2,4,5 --- -/--	1-11
X		1-11

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
